**ABSTRACT**

An electronic device includes a substrate wafer made of many layers of an insulating material and including an electrical connection network. An integrated circuit chip is mounted to a top side of the substrate wafer. The substrate wafer further includes a metal plate that is integrated into the substrate wafer and thermally coupled to the integrated circuit chip. The metal plate may have a thickness in excess of several layers of the substrate wafer. The metal plate may include a duct through which a thermally conductive fluid flows.

# INTEGRATED CIRCUIT CHIP COMPRISING ELECTRONIC DEVICE AND ELECTRONIC SYSTEM

## PRIORITY CLAIM

This application claims priority from French Application for Patent No. 1360007 filed Oct. 15, 2013, the disclosure of which is incorporated by reference.

## TECHNICAL FIELD

The present invention relates to the field of microelectronics.

## BACKGROUND

It is known to make electronic systems that comprise electronic devices stacked one on top of the other and electrically connected together, including at least one integrated circuit chip respectively.

Stacking electronic devices in particular has the advantage of improving the performance of electrical connections and of reducing footprint. Nevertheless, in certain cases integrated circuit chips may produce heat and the heat produced may heat other integrated circuit chips and thus degrade the performance of the latter. This is especially the case when a first electronic device comprises a processor chip that produces heat, and a second electronic device stacked on the first comprises a memory chip, the operation of which in particular degrades when its temperature increases.

The above circumstances are an obstacle to increasing the performance of said electronic systems, such as in particular the speed at which they run programs. However, the situation that at the present time consists in making a compromise between the performance desired from said electronic systems and their footprint, is unsatisfactory, especially in the field of portable devices such as mobile phones.

## SUMMARY

According to one embodiment, an electronic device is provided, which comprises a substrate wafer made of an insulating material, which wafer is equipped with an electrical connection network and which bears, on one side, at least one integrated circuit chip, and which device comprises at least one metal plate integrated into said substrate wafer.

A plurality of intermediate metal elements and a plurality of external metal elements may be placed on either side of the substrate wafer.

Said intermediate metal elements may comprise first intermediate metal elements connecting said chip and said electrical connection network, and second intermediate metal elements connecting said chip to said metal plate.

Said external metal elements may comprise first metal elements connected to said electrical connection network and second external metal elements connected to said metal plate.

Said metal plate may lie between intermediate metal levels of said electrical connection network.

Said metal plate may be connected to said second intermediate metal elements by metal vias.

Said metal plate may be connected to said second external metal elements by metal vias.

Said metal plate may comprise protrusions on which said second intermediate metal elements are placed.

Said metal plate may comprise protrusions on which said second external metal elements are placed.

2

Said metal plate may contain at least one internal duct filled with a thermally conductive material.

Said substrate wafer may contain ducts connected to said internal duct of said metal plate and connected to means for making a fluid flow.

An electronic system is also provided, which comprises said electronic device, and which comprises another electronic device placed on said electronic device and comprising another substrate wafer equipped with another electrical connection network connected to said electrical connection network and bearing at least one other integrated circuit chip connected to this other electrical connection network.

Said system may comprise a printed circuit board bearing said electronic device by way of external metal elements.

## BRIEF DESCRIPTION OF THE DRAWINGS

Electronic devices and electronic systems, according to particular embodiments of the present invention, will now be described by way of nonlimiting example, these devices and systems being illustrated by the drawings, in which:

FIG. 1 shows a cross section of an electronic device;

FIG. 2 shows a cross section of an electronic system including the electronic device in FIG. 1;

FIG. 3 shows a variant embodiment of the electronic device in FIG. 1; and

FIG. 4 shows another variant embodiment of the electronic device in FIG. 1.

## DETAILED DESCRIPTION OF THE DRAWINGS

As illustrated in FIG. 1, an electronic device 1 comprises a substrate wafer 2 equipped with an integrated metal electrical connection network 3 connecting one side to the other, an integrated circuit chip 4 placed on one side of the substrate wafer 2, a plurality of intermediate metal electrical connection elements 5 such as columns, and a plurality of external metal electrical connection elements 6, such as bumps, placed on either side of the substrate wafer 2.

In the example shown, the integrated electrical connection network 3 comprises, from the top of the substrate wafer, six separate metal levels M1, M2, M3, M4, M5 and M6 parallel to the sides of the substrate wafer 2, which levels respectively comprise metal pads selectively connected by interlevel metal electrical connection vias.

Furthermore, the electronic device 1 comprises at least one metal plate 7 integrated or incorporated into the substrate wafer 2 and separate from the metal electrical connection network 3.

In the example shown, the thickness of the metal plate 7 is such that it occupies the thickness comprised between the intermediate metal levels M2 and M5.

The plurality of intermediate metal elements 5 comprises first intermediate metal elements 5a connecting the chip 4 and the electrical connection network 3, and interposed between metal pads of the chip 4 and metal pads 8a of the metal level M1 of this electrical connection network 3.

The plurality of intermediate metal elements 5 also comprises second intermediate metal elements 5b interposed between the chip 4 and metal pads 8b of the metal level M1 of the electrical connection network 3.

In the metal level M2, metal pads 9b are arranged on the corresponding side 7a of the metal plate 7.

Metal vias 10b are arranged between metal pads 8b of the metal level M1, and metal pads 9b of the metal level M2.

3

The plurality of external metal elements **6** comprises first external metal elements **6a** placed on metal pads **11a** of the metal level M6 of the electrical connection network **3**.

The plurality of external metal elements **6** also comprises second external metal elements **6b** placed on metal pads **11b** of the metal level M6 of the electrical connection network **3**.

In the metal level M5, metal pads **12b** are arranged on the corresponding side **7b** of the metal plate **7**.

Metal vias **13b** are arranged between metal pads **11b** of the metal level M6, and metal pads **12b**.

According to one embodiment, the integrated circuit chip **4**, which may be a processor chip, may generate heat. At least some of this heat may preferentially be transferred to the metal plate **7** integrated into the substrate wafer **2** by way of the second intermediate metal elements **5b**, the metal pads **8b**, the metal vias **10b** and the metal pads **9b**.

Thus, the integrated or incorporated metal plate **7**, because of its relatively large volume, acts as a heat sink or a heat pump and forms a heat transfer means, in such a way that the chip **4** is cooled.

Thus, at least some of this heat may be transferred to the second external metal elements **6b**.

The electrical connection elements **5b** used to preferentially evacuate the heat may be chosen so that they are located in a localized zone of the chip **4** producing the most heat.

Some of the heat produced by the chip **4** may also be transferred to the electrical connection network **3** by way of the electrical connection elements **5a**, then transferred to the electrical connection elements **6a**.

Moreover, in the metal level M1, are arranged auxiliary metal pads **8c** located on the periphery of the chip **4**, and on which are placed auxiliary metal elements **14**.

The electronic device **1** may furthermore comprise an encapsulating layer **15** provided on the substrate wafer **2** and around the chip **4**, this layer **15** containing holes **16** in which auxiliary metal electrical connection elements **14**, such as metal bumps, are placed.

As illustrated in FIG. 2, an electronic system **100** may comprise the electronic device **1** in FIG. 1, and another electronic device **101** stacked on the electronic device **1** on the same side as the chip **4**.

According to one example embodiment, the electronic device **101** comprises a substrate wafer **102** equipped with an electrical connection network **103** connecting one side to the other, and furthermore bears an integrated circuit chip **104** bonded to that side opposite the electronic device **1**.

The chip **104** is connected to the electrical connection network **103** by metal wires **105**.

The chip **104** and the electrical connection wires **105** are embedded in an encapsulation material **106** provided on the corresponding side of the substrate wafer **102**.

The electronic device **101** is mounted on the electronic device **1** by way of electrical connection elements **107** such as metal bumps, which elements **107** are interposed between said devices, and electrically and selectively connect the electrical connection network **103** of the electronic device **101** to the electrical connection network **3** of the electronic device **1** by being soldered to electrical connection elements **14** placed on the pads **8c**.

Furthermore, the electronic device **1**, and therefore the electronic system **100**, is mounted on a printed circuit board **108** by way of electrical connection elements **6** soldered to metal pads **109** of this board **108**.

The arrangement described above by way of example has the following advantages.

The chip **104**, which may be a memory chip, is set away from the chip **4** and is separated from the latter by the sub-

4

strate wafer **102** and by the space separating the electronic device **1** and the electronic device **101**.

The heat produced by the chip **4** and transferred to the connection elements **6a** and, preferentially, to the electrical connection elements **6b** as described above, diffuses into the printed circuit board **108**.

The heat produced by the chip **4** also diffuses into the space separating the electronic device **1** and the electronic device **101**, in order to be evacuated toward the exterior.

It follows from the foregoing description that the metal plate **7** forms a means for capturing at least some of the heat produced by the chip **4**, and a means for transferring heat away from the chip **104**.

Thus, diffusion of the heat produced by the chip **4** toward the chip **104** is limited in such a way that the chip **104** is protected from any excessive increase in its temperature.

Moreover, as the metal elements **5b** connected to the chip **4** are connected to the metal elements **6b**, in particular by way of the metal plate **7**, this connection may be used for electrical purposes, for example in order to form a connection to electrical ground.

According to one variant embodiment of the electronic device **1**, which variant is illustrated in FIG. 3, the metal pads **8b** of the metal level M1, the metal pads **9b** of the metal level M2 and the metal vias **10b** connecting them together may be replaced, at least in part, by protrusions **17** in the metal plate **7**, protruding relative to its side **7a**, the electrical connection elements **5b** making contact with said protrusions **17**.

Likewise, the metal pads **11b** of the metal level M6, the metal pads **12b** of the metal level M5 and the metal vias **13b** connecting them together may be replaced, at least in part, by protrusions **18** in the metal plate **7**, protruding relative to its side **7b**, the electrical connection elements **6b** making contact with said protrusions **18**.

According to one variant embodiment of the electronic device **1**, which variant is illustrated in FIG. 4, the metal plate **7** is replaced by a metal plate **19** integrated between the intermediate metal levels M3 and M4 of the electrical connection network **3**.

In the metal level M3, metal pads **20b** are arranged on the side **19a** of the metal plate **19**, which pads **20b** are connected to the metal pads **9b** of the metal level M2 by metal vias **21b**.

Likewise, in the metal level M4, metal pads **22b** are arranged on the side **19b** of the metal plate **19**, which pads **22b** are connected to the metal pads **12b** of the metal level M5 by metal vias **21b**.

According to one variant embodiment, the metal plate **19** may contain internal ducts **24** that may be filled with a thermally conductive or heat transfer fluid such as a polyalpha-olefin or one of the FC electronic liquids sold under the name or trademark Fluorinert.

According to one variant embodiment, the internal ducts **24** may be connected to ducts **25**, for example supply/return ducts, for example arranged in the layer of the substrate wafer **2** separating the metal levels M3 and M4, these ducts **25** emerging laterally from the substrate wafer **2** and possibly being connected to external means suitable for making a cooling fluid flow through the ducts **24**.

According to another variant embodiment, the electronic device **1** may be equipped with a component incorporating a micropump, which component may be fixed to one of the sides of the device, for example by bonding, this micropump being connected to the internal ducts **25** by suitable passages, in order to make the heat transfer or cooling fluid flow through the internal ducts **24** of the metal plate.

Thus, evacuation of the heat produced by the chip **4** may be even further improved.

5

The metal plates 7 and 19 may extend over a zone corresponding approximately to a small zone of the chip 4 producing the heat, or over a larger zone corresponding approximately to the total zone of the chip, or over a zone protruding laterally relative to the chip 4.

The present invention is not limited to the examples described above. In particular, the structure of the device 101 could be different. The metal plate could lie between other metal levels. More than one metal plate could be provided. Other heat capturing, heat transfer and cooling means including a metal plate integrated into the substrate could be provided. Many other variant embodiments are possible without departing from the scope of the invention.

What is claimed is:

1. An electronic device, comprising:
  - a substrate wafer made of an insulating material and including an electrical connection network extending between a first face and a second face, said electrical connection network having a plurality of metal levels connected by vias;
  - at least one integrated circuit chip mounted on the first face of the substrate wafer;
  - a plurality of intermediate metal elements configured to mount the integrated circuit chip to the substrate wafer;
  - a plurality of external metal elements mounted on an opposite side of the substrate wafer;
  - a metal plate integrated into said substrate wafer and lying between intermediate ones of said metal levels, wherein the metal plate comprises protrusions extending from the metal plate through the substrate wafer and thermally connected to the plurality of intermediate metal elements and the plurality of external metal elements.
2. The electronic device according to claim 1, wherein said intermediate metal elements comprise: first intermediate metal elements connecting said integrated circuit chip to said electrical connection network and second intermediate metal elements connecting said integrated circuit chip to the metal plate; and
  - wherein said external metal elements comprise first metal elements connected to said electrical connection network and second external metal elements connected to said metal plate.
3. The device according to claim 2, wherein said second intermediate metal elements are placed on the protrusions of the metal plate.
4. The device according to claim 3, wherein said second external metal elements are placed on the protrusions of the metal plate.
5. The device according to claim 1, wherein said metal plate contains at least one internal duct filled with a thermally conductive material.
6. The device according to claim 5, wherein said substrate wafer contains ducts connected to said internal duct of the metal plate, said ducts configured for connection to an external means for making a fluid flow through the ducts and internal duct.

6

7. The device according to claim 1, wherein said substrate wafer comprises a multiplicity of layers and wherein said metal plate has a thickness which is thicker than a plurality of said layers.

8. The device according to claim 1, further comprising another substrate wafer having another electrical connection network that is connected to said electrical connection network and including at least one other integrated circuit chip connected to the another electrical connection network.

9. The device according to claim 8, further comprising a printed circuit board to which the substrate wafer is mounted using external metal elements.

10. The electronic device of claim 1, further comprising an encapsulation layer encapsulating the substrate wafer, the encapsulation layer coplanar with the integrated circuit chip.

11. An electronic device, comprising:
 

- an integrated circuit chip having first contacts;
- a substrate wafer made of a multiplicity of layers and having a top surface with top contact pads and a bottom surface with bottom contact pads;
- wherein said integrated circuit chip is mounted to the substrate wafer with the first contacts connected to the top contact pads; and
- said substrate wafer further including a metal body including: a metal plate embedded between intermediate ones of the multiplicity of layers within the substrate wafer, a first metal region protruding from the metal plate through layers of the substrate wafer to reach the top surface of the substrate wafer and a second metal region protruding from the metal plate through layers of the substrate wafer to reach the bottom surface of the substrate wafer.

12. An electronic device, comprising:
 

- an integrated circuit chip having first contacts;
- a substrate wafer made of a multiplicity of layers and having a top surface with top contact pads and a bottom surface with bottom contact pads;
- wherein said integrated circuit chip is mounted to the substrate wafer with the first contacts connected to the top contact pads; and
- said substrate wafer further including a metal plate embedded between intermediate ones of the multiplicity of layers within the substrate wafer; wherein the metal plate further comprises a protrusion extending through the multiplicity of layers of the substrate wafer to reach the bottom contact pads of the bottom surface;
- said metal plate including an internal duct filled with a thermally conductive material;
- wherein the metal plate is thermally connected to the integrated circuit chip.

13. The device of claim 12, wherein said substrate wafer further includes a duct extending through the substrate wafer and in fluid communication with the internal duct of the metal plate.

14. The device of claim 13, wherein said duct extending through the substrate wafer is configured for connection to an external means for making a thermally conductive fluid flow through the duct and internal duct.

3. The device according to claim 2, wherein said second intermediate metal elements are placed on the protrusions of the metal plate.

4. The device according to claim 3, wherein said second external metal elements are placed on the protrusions of the metal plate.

5. The device according to claim 1, wherein said metal plate contains at least one internal duct filled with a thermally conductive material.

6. The device according to claim 5, wherein said substrate wafer contains ducts connected to said internal duct of the metal plate, said ducts configured for connection to an external means for making a fluid flow through the ducts and internal duct.

7. The device according to claim 1, further comprising another substrate wafer having another electrical connection network that is connected to said electrical connection network and including at least one other integrated circuit chip connected to the another electrical connection network.

8. The device according to claim 7, further comprising a printed circuit board to which the substrate wafer is mounted using external metal elements.

9. The electronic device of claim 1, further comprising an encapsulation layer encapsulating the substrate wafer, the encapsulation layer coplanar with the integrated circuit chip.

10. An electronic device, comprising:  
an integrated circuit chip having first contacts;  
a substrate wafer made of a multiplicity of layers and having a top surface with top contact pads and a bottom surface with bottom contact pads;

wherein said integrated circuit chip is mounted to the substrate wafer with the first contacts connected to the top contact pads; and

said substrate wafer further including a metal body including: a metal plate embedded between intermediate ones of the multiplicity of layers within the substrate wafer, a first metal region protruding from the metal plate through layers of the substrate wafer to reach the top surface of the substrate wafer and a second metal region protruding from the metal plate through layers of the substrate wafer to reach the bottom surface of the substrate wafer, wherein said metal plate has a thickness thicker than at least two of the multiplicity of layers and a uniform cross sectional width immediately between the first and the second metal regions.--
